The present invention relates to natural gas fired engines. In particular, the invention relates to a variable displacement engine which operates at a constant mass

flow rate during a first portion of a power cycle but which automatically regains a constant power output during a second portion of the power cycle. Natural gas fueled engines, such as reciprocating or rotary engines, are used in a wide variety of applications, including heavy duty applications such as powering machinery, or may be used to power turbines or electric generators. In engines operated in a thermal mode, the air intake is throttled so that the amount of air is limited to the amount required to support combustion. The air supplied to the engine is compressed and mixed with fuel in a chamber. Heat from the compressed air and fuel is transferred to a piston. Once the piston has reached a predetermined temperature or point along its power stroke, the piston compresses a fresh charge of air and fuel in the combustion chamber. The expansion of the fuel and air produces a thrust force which accelerates the piston to the next power stroke. Power is extracted from the engine by transferring power from the expanding gases through a connecting rod to the crankshaft of the engine. Engine efficiency varies inversely with engine displacement. Thus, engine displacement is generally increased to achieve higher thermal efficiencies at higher engine speeds. However, for various reasons, it may be desirable to operate an engine at maximum continuous power for an extended period of time, but also at a constant mass flow rate or a constant power output. For example, it may be desirable to operate a heavy duty engine at continuous maximum power for extended periods to drive an electric generator during normal operation of a plant, but to operate the engine at a constant maximum power for a short time interval to power auxiliary

equipment such as a battery charger. If the engine is operating at constant maximum power, the mass flow rate of the engine (and thus the engine output power) may be increased simply by increasing the size of an intake throttle. However, once the throttling is increased, the engine must be throttled back down again to prevent the engine from exceeding a predetermined mass flow rate. Also, the mass flow rate of the engine during the power output interval may be increased by throttling the air intake, which in turn reduces the average mass flow rate of the engine. Mechanisms for controlling a power output of an engine at a constant power are known in the art. However, these mechanisms are difficult to control in practice and are limited in application. Accordingly, there is a
